

Problem 1 - Washing Machine Mount Design

The Matlab code for this problem is listed in Appendix 1.

Problem 1a

Equation calculates the force produced by the imbalanced 1kg mass at a 0.5 m radius from the center of the washing machine as a function of angular velocity,

$$F = m \cdot \omega^2 \cdot r \quad (1)$$

where m is 0.5 kg, ω is the angular velocity in $\frac{\text{radians}}{\text{s}}$, and r is 0.5 m.

Figure 1 shows the force produced by the 1 kg load as a function of angular velocity in RPM.

Figure 1: Load force versus washing machine angular speed.

At 300 RPM, or 5 Hz, the imbalanced load force amplitude is 493.5 N.

Problem 1b

The required spring stiffness, k_s , is $9,810 \frac{\text{N}}{\text{m}}$. The mount's natural frequency, w_o , is 1.5 Hz.

Problem 1c

Figure 2 shows the transmission loss of the system for a set of damping ratios ranging from 0.001 to 1.

Figure 2: Transmission loss as a function of damping ratio. The natural frequency is 1.5 Hz.

Problem 1d

Figure 3 shows the force applied to the foundation.

Figure 3: Force applied to the foundation as a function of damping ratio.

No damping ratio makes the applied force less than 100 N across the 0 to 350 RPM operating range.

The best damping ratio is $\zeta = 0.25$. The force applied to the foundation still exceeds the 100 N target in only two small RPM regions: 91 to 109, and 331 to 350 RPM. In both of these regions the force is approximately 104 N.

Problem 1e

The viscous damping coefficient is $519.4 \frac{\text{kg}}{\text{s}}$ based on a total mass of 110 kg.

Figure 4 shows the admittance.

Figure 4: Admittance versus RPM.

The admittance at 300 RPM is $10^{-5} \frac{\text{m}}{\text{N}}$.

Problem 1f

Figure 5 shows the displacement of the washing machine.

Figure 5: Displacement versus RPM.

The displacement of the washing machine at 300 RPM is approximately 4.9×10^{-3} m. The washing machine undergoes larger momentary displacements as it spins up to 300 RPM, in particular around 100 RPM.

Problem 2 - Washing Machine Mount Design (2 DOF)

The Matlab code for this problem is listed in Appendix 2.

Problem 2a

Figure 1 illustrates the two-stage vibration mount showing the washing machine and the “raft”.

Figure 1: Two-stage vibration mount system for the washing machine.

Problem 2b

Table 1 lists the initial stiffness and damping coefficients for the system.

M1	110	kg
K1	100	$\frac{N}{m}$
C1	5	$\frac{kg}{s}$ ¹

M2	100	kg
K2	100	$\frac{N}{m}$
C2	5	$\frac{kg}{s}$ ²

M3	0	kg
K3	1,000	$\frac{N}{m}$
C3	0	$\frac{kg}{s}$ ³

Table 1: Initial values of stiffness and damping coefficients.

Damping was implemented using the damping vector⁴.

¹Element of damping vector.

²Element of damping vector.

³Element of damping vector.

⁴Not equivalent to using a complex-valued stiffness vector; the imaginary part is the damping for the respective spring

Problem 2c

Figure 2 shows the admittance of the washing machine and the raft.

Figure 2: Admittance of the washing machine and the raft with a force on the washing machine.

The admittance of the washing machine is $9.31 \times 10^{-6} \frac{\text{m}}{\text{N}}$ at 300 RPM.

Problem 2d

Figure 3 show the displacement of the washing machine and the raft.

Figure 3: Displacement of the washing machine and the raft with a force on the washing machine.

At 300 RPM, the washing machine displacement is $4.6 \times 10^{-3} \text{ m}$, less than $5.0 \times 10^{-3} \text{ m}$ for the first-order system. The displacement of the raft is $4.7 \times 10^{-5} \text{ m}$.

Problem 2e

Figure 4 shows the force applied to the ground by the raft.

The force is calculated by multiplying the displacement of the raft by the K_2 spring constant.

Figure 4: Force applied to the ground by the raft.

The ground force at 300 RPM is 4.7×10^{-3} N. The force on the ground is always less than 100 N.

Problem 2f

The performance of this system was improved by *lowering the stiffness of the coupling spring*, k_3 . Lowering k_3 decreases the separation of the two resonance peaks and shifts them down in frequency. This results in lower admittances for the washing machine and the raft at 300 RPM. However, due to the quadratic characteristic of the load force with RPM and the second-order roll-off of the admittance curve for the washing machine, optimization is restricted.

In Figure 3, displacement of the washing machine after the second resonance frequency “plateaus” with much less roll-off relative to the raft displacement. This restricts the degree of optimization that can be done in this case.

Problem 2g

Table 2 compares the admittance, displacement, and ground force for the initial and optimized systems.

	Admittance [$\frac{\text{m}}{\text{N}}$]	Displacement [m]	Ground Force [N]
Initial Design	9.31×10^{-3}	4.59×10^{-3}	4.7×10^{-3}
Optimized Design	9.22×10^{-6}	4.55×10^{-3}	4.62×10^{-5}

Table 2: Performance comparison of the initial and optimized designs.

The initial parameter set chosen, see Table ??, facilitated a displacement of the washing machine of 4.6×10^{-3} m at 300 RPM, which is less than the 5.0×10^{-3} m found for the 1 DOF system. The force applied to the ground by the raft is less than the required 100 N maximum.

Problem 3 - Washing Machine Dynamic Vibration Absorber Design

The Matlab code for this problem is listed in Appendix 3.

Part 3a

Figure 1 illustrates the dynamic vibration absorber (DVA) system.

Figure 1: Dynamic vibration absorber system for the washing machine.

Table 3 lists the stiffness and damping coefficients for the system.

M1	15	kg
K1	0	$\frac{\text{N}}{\text{m}}$
C1	0	$\frac{\text{kg}}{\text{s}}$

M2	110	kg
K2	9,810	$\frac{\text{N}}{\text{m}}$
C2	1,962	$\frac{\text{kg}}{\text{s}}$ ⁵

M3	0	kg
K3	1e5	$\frac{\text{N}}{\text{m}}$
C3	1e4	$\frac{\text{kg}}{\text{s}}$ ⁶

Table 3: Stiffness and damping coefficients for the DVA system.

Damping was implemented by adding with an imaginary component to the respective spring stiffness⁷.

⁵0.2 fraction of respective spring stiffness.

⁶0.1 fraction of respective spring stiffness.

⁷Not equivalent to using a damping vector in the argument to the given Matlab nDOF function script-file.

Part 3b

Figure 2 shows the admittance response of the original system and DVA system based on the equations presented in the tutorial lecture on DVA system analysis.

Figure 2: Admittance responses based on the equations from the DVA tutorial lecture.

The washing machine admittance at 300 RPM is reduced from the blue curve resonance peak to a point between the two resonances on the red curve).

Part 3c - Admittance

Figure 3 shows the admittance response of the DVA system using the nDOF function script-file. The stiffness of the coupling spring, k_3 , is set to place the null of the admittance response at the 300 RPM operating state of the washing machine. *The admittance at 300 RPM is approximately $1.2 \times 10^{-6} \frac{m}{N}$.*

Figure 3: Solution using nDOF script-file function.

Part 3d - Displacement

Figure 4 shows the displacement of the washing machine as a function of RPM. The ramp up to 300 RPM occurs quickly so that the large displacements are transient and the maximum speed is 350 RPM (the large displacement associated with the resonance peak at higher frequencies is not reached). *The displacement at 300 RPM is approximately 38.2×10^{-6} m.*

Figure 4: Displacement of the washing machine.

Part 3e

Figure 5 shows the force applied to the floor by the washing machine. *The force applied to the floor at 300 RPM is approximately 3.75×10^{-3} m.*

Figure 5: Force applied to the floor.

Problem 4 - Washing Machine Abuse Testing

The Matlab code for this problem is listed in Appendix 4.

Part 4a

11 %% Synopsis
12
13 % Problem 3 – Washing Machine Dynamic Vibration Absorber (DVA) Design
14
15
16
17 %% Note(s)
18
19 % At 300 RPM, the load frequency, this system will isolated vibration more
20 % than the 2 DOF and 1 DOF systems.
21
22 % The DVA behaves like a Helmholtz resonator, working as a mechanical notch
23 % filter at a particular frequency.
24
25 % DVAs work well in systems that have one dominate mode. A good
26 % example of this is building sway and its compensation. Based on the
27 % design and construction of a building, it will typically have a single,
28 % dominate mode.
29
30 % DVA is useful if you can not get away from the resonance frequency; can
31 % not tune a 2 DOF system when the resonance frequency is away from the
32 % forcing frequency.
33
34 % DVA introduces two resonances for the original resonance. These new
35 % resonances will produce greater motion at the new resonance frequencies.
